This post is to inform readers about a new and improved version of interactive petrophysics, an award-winning software program. It is now available for download at our website. The new and improved version improves the sustainability of this software by supplying it with state-of-the-art algorithms as well as providing it with a more accurate algorithm for calculating static fluid content (SFC). This breakthrough has created a more useful and accurate program that can aid in any type of drilling or production scenario. The post will also provide readers with information on how to use the software as well as what makes this software different from other popular software programs on the market.

What Is Interactive Petrophysics? Interactive Petrophysics is a software program that was developed by a team of petroleum engineers, geologists and geophysicists. It is a computer software package that contains a comprehensive collection of rock property, rock physics and fluid property data. The package can be used to solve any type of production engineering problem like finding oil or gas, finding water zones in unconsolidated sands, predicting the productivity of existing producing wells, predicting the petrophysical properties of rocks prior to drilling or improving recovery from existing wells. The software allows the user to see how changing one physical property causes an instant change in other physical properties like porosity. Originally, the software was designed for use by petroleum engineers in the early 1980s, but today it is used by many types of professionals in many different fields all over the world. What Are Its Main Features? Interactive Petrophysics will calculate a wide variety of physical properties for a rock or fluid. The software allows the user to input data in either English or SI units and can run on Windows operating systems from 95 to 7, 10 and Mac OSX. The software also allows the user to input existing production well information from almost any type of wells. This method makes it easier and more convenient than using different tables and charts that can be hard to read and memorize. This software is also capable of solving complex petrophysical problems that require a variety of different properties to be calculated. The program does not display a list of the physical properties, but uses a color gradient to represent the values of each physical property which makes it easier for the user to see what is going on in the calculation. Difficult cases involving complex geological or fluid systems can be easy to solve using this program. To solve these types of cases, the user will first need to map out all relevant parameters for this system. The software will then calculate multiple different scenarios for these parameters and use them to create multiple lithofacies models until it finds just one that fits with all relevant information. For example, one of the first problems that interactive petrophysics was used to solve was predicting the porosity and permeability of rocks and to consider their other physical properties like density and thermal conductivity. What Makes This Software Different from Other Popular Software Programs? The main difference between this software and other popular software programs is the way that they calculate the values of rock physical properties. In most rock property software, a user can enter a single value for a physical property like porosity or SFC and have it calculate all other values based off this single value. In interactive petrophysics, a user can input multiple different physical properties related to one another at once and obtain more accurate results.
