Alterations in the viscosity and elasticity of plasma due to the addition of a surfactant. The viscosity and elasticity of the plasma fluid can be altered by the addition of a surfactant. These effects, in principle, could be of use in facilitating the formation of bubbles in a wide variety of artificial or biological systems, including the lungs and bloodstream, where a concentration gradient is present for the surfactant to bind with. This study quantifies the viscosity and elasticity of human plasma as a function of surfactant concentration, and discusses the implications of these effects on the stability of bubbles. The results show that the elasticity and viscosity of plasma vary by two orders of magnitude depending on the concentration of surfactant. The addition of a single surfactant (cetyltrimethylammonium bromide, CTAB) causes a decrease in both the viscosity and elasticity of plasma. This can be explained by an association of the surfactant with the interface of the plasma protein layer, increasing the mobility of the proteins at the interface. This is consistent with the decrease in the electrical conductivity of plasma seen with the addition of CTAB. The addition of several surfactants, to give a total surf a1d647c40b
