I have a large number of classes in a local directory in my project. I want to somehow automatically add this directory to the classpath, since I can't remember all the individual jars. I would rather not manage those and keep it in one directory. A: If it's just a few directories you can probably do something like: \$ find. -type f -exec java -jar YOUR_JAR {} \; If it's a lot, and you can write a script that calls itself recursively, or whatever you want to do, you can pass the results of find as argument to a script. A: If you have put the JARs into a directory structure, you can set up a Jar file that will read it's own classpath, and read that directory in. 16:11:38.20,0:16:11.29 # 2020 2020 0:16:12.28,0:16:12.37 # 222222 22222 0:16:12.37,0:16:12.42 # 2222 2222 0:16:12.42,0:16:12.70 # ???????????????????

A utility that allows you to create multiple multi-boot USB drives that contain both a Windows and Linux operating systems. It features UEFI support and creates ISO images that are portable, easy to use and highly compatible with Windows and Linux.It is well known in the art of internal combustion engines to provide an exhaust gas recirculation system which reduces the amount of noxious exhaust emissions emitted by the engine. Typical recirculation systems recycle a portion of the exhaust gases from the engine back into the engine cylinders to reduce the concentration of oxygen in the cylinders and thereby reduce the amount of NOx formed during the combustion process. It is known in the art of four-stroke internal combustion engines to provide a recirculation system using an exhaust gas recirculation (EGR) valve mounted in the exhaust manifold which directs a portion of the engine exhaust back through the air intake manifold and into the exhaust pipe. The volume of exhaust gases returned to the engine through the EGR valve is typically controlled using a pulse width modulated (PWM) control device which opens or closes the valve for a fraction of each cycle. One such control device is disclosed in U.S. Pat. No. 5,617,821, issued Apr. 8, 1997 to James D. Smith which is assigned to the assignee of the present invention and incorporated herein by reference. The control device disclosed therein comprises a PWM controller which receives a feedback signal representative of engine back pressure and directs a current to an EGR valve in response to the feedback signal and a drive signal. The drive signal is a pulse-width-modulated (PWM) analog signal which is cyclically switched between a minimum and a maximum voltage level by the PWM controller and which periodically activates and deactivates the EGR valve. A drawback of this known control device is that the controller requires a minimum amount of current to be applied to the EGR valve in order to open and close the valve. One factor affecting the amount of current necessary to open the valve is the amount of current in the switch which is used to apply the drive signal to the EGR valve. Depending on the switching configuration of the switch, it may be difficult to provide a sufficiently low current to open the valve. It would be desirable to have a low current switch which does not require a large amount of current to both open and close the EGR valve. Another factor affecting the current in the switch is the power dissipated in the switch. It would also be desirable to have a low current
